Understanding the NIHSS Stroke Scale

What is the NIHSS?

The National Institutes of Health Stroke Scale (NIHSS) is a standardized clinical assessment tool designed to quantify the neurological deficits caused by a stroke. Developed in 1989 and later refined, the NIHSS provides a systematic way to evaluate the severity of stroke symptoms, ranging from minor deficits to profound impairments. Its widespread adoption stems from its validated reliability, ease of use,

and prognostic significance. The scale encompasses various domains of neurological function, including consciousness, gaze, visual fields, motor and sensory function, language, and cerebellar function. Each domain is scored individually, and the combined total score reflects the overall stroke severity.

Why is the NIHSS important?

The NIHSS serves multiple critical purposes in stroke management: - Initial assessment: Rapidly determining stroke severity at presentation. - Treatment decisions: Guiding interventions such as thrombolysis or mechanical thrombectomy. - Monitoring progression: Tracking changes over time to assess response to treatment. - Prognostication: Estimating functional outcomes and guiding rehabilitation planning. - Research and data collection: Standardized scoring facilitates consistency across studies and clinical audits.

The Structure of the NIHSS

The NIHSS comprises 15 items, each scored on a scale from 0 (normal function) to varying maximum points indicating severity. The total score ranges from 0 to 42, with higher scores indicating more severe neurological impairment.

Section breakdown:

1. Level of Consciousness (LOC) - Assesses alertness, responsiveness, and ability to follow commands. 2. Orientation Questions and Commands - Evaluates orientation to time and space, and motor response. 3. Gaze - Tests voluntary eye movement and gaze deviation. 4. Visual Fields - Checks for visual field deficits, such as hemianopia. 5. Facial Palsy - Assesses facial muscle strength for asymmetry. 6. Motor Arm (Left and Right) - Measures arm strength and drift. 7. Motor Leg (Left and Right) - Evaluates leg movement and strength. 8. Limb Ataxia - Tests coordination. 9. Sensory - Assesses sensation to pinprick or light touch. 10. Language - Evaluates aphasia or dysarthria. 11. Speech - Checks for clarity and comprehension. 12. Extinction and Inattention (Neglect) - Detects neglect or sensory extinction. Each item is scored based on specific criteria, which are detailed in standardized protocols. The total score guides clinical decision-making and prognosis.
