Fundamentals of Wavelength Division Multiplexing (WDM)

What is WDM?

Wavelength Division Multiplexing (WDM) is a technology that combines multiple optical carrier signals, each at a different wavelength (or color), onto a single optical fiber. This allows multiple data streams to be transmitted simultaneously, vastly increasing the fiber's capacity without the need for additional fibers.

Principle of Operation

The core principle of WDM involves dividing the optical spectrum into discrete wavelength channels. Transmitters modulate data onto their respective wavelengths, which are then combined using wavelength multiplexers. At the receiver end, demultiplexers separate the channels for individual processing. The key advantage is the ability to scale bandwidth linearly by adding more wavelengths, known as channels.
