Meiosis I: Reductional Division

1. Prophase I - Homologous chromosomes pair up (synapsis) - Crossing over may occur, exchanging genetic material - Key Point: This increases genetic diversity and creates recombinant chromosomes 2. Metaphase I - Homologous pairs align at the cell's equator - Spindle fibers attach to each homologous chromosome - Key Point: Independent assortment begins here 3. Anaphase I - Homologous chromosomes are pulled apart to opposite poles - Sister chromatids remain attached - Key Point: Reduction of chromosome number from diploid to haploid 4. Telophase I and Cytokinesis - Two haploid cells are formed - Each contains homologous chromosomes still composed of sister chromatids

Meiosis II: Equational Division

1. Prophase II - Chromosomes condense again in each haploid cell - Spindle fibers form anew 2. Metaphase II - Chromosomes align at the metaphase plate - Spindle fibers attach to sister chromatids 3. Anaphase II - Sister chromatids are separated and pulled to opposite poles 4. Telophase II and Cytokinesis - Four haploid gametes are produced - Each gamete contains a unique combination of genetic material

Meiosis Overview

Meiosis is a specialized form of cell division that reduces the chromosome number by half, producing haploid gametes from diploid germ cells. It comprises two consecutive divisions: - Meiosis I: Homologous chromosomes pair and segregate, with crossing over occurring during prophase I. - Meiosis II: Similar to mitosis, sister chromatids separate. Key features include: - Homologous chromosome pairing and crossing over. - Independent assortment resulting in genetic variation. - Reductional division in meiosis I.
